# Assignment 2 - Scientific Computing SC9505

Jared Wogan

2022-11-21

All code was compiled inside an Ubunutu WSL environment on an AMD 3900X with 32GB of RAM. All timing are performance data was run with dense, randomly generated arrays and vectors. A full repository containing all of my code can be found at https://github.com/JaredWogan/SC9505.

#### 1 Matrix Vector Multiplication Using MPI

Our first exercise is to determine the benefits of parallelization on a code that computes a matrix vector product. We first test the code ensuring that it is giving correct results, as can be seen in Figure 1.

```
* (base) jared@Nebulae:.../Scientific Computing SC9505/Assignment 2 - November 30/MV$ make clean
rm -rf 15-matrix-vector.o 16-serial.o

mpiCC -02 -o 16-serial.o 11-serial-matrix-vector.gp

mpiCc -02 -o 16-serial.o 11-serial-matrix-vector.gp

* (base) jared@Nebulae:.../Scientific Computing SC9505/Assignment 2 - November 30/MV$ mpirun -n 4 ./15-matrix-vector.o 1 10 10

Average calculation time = 0.0001055470
(0, 1, 2, 3, 4, 5, 6, 7, 8, 9)

* (base) jared@Nebulae:.../Scientific Computing SC9505/Assignment 2 - November 30/MV$ mpirun -n 8 ./15-matrix-vector.o 1 20 20

Average calculation time = 0.0003046000

(0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19)

* (base) jared@Nebulae:.../Scientific Computing SC9505/Assignment 2 - November 30/MV$
```

Figure 1: Demonstration of the code working. Here the matrix is taken to be the identity, and the vector is filled with consecutive integers.

The scaling when the program is run on 4 threads as a function of the number of rows/columns was determined to be  $\mathcal{O}(N^{1.5})$ , see Figure 2. This is less than is expected for matrix vector multiplication, which is typically an  $\mathcal{O}(N^2)$  operation. The serial code I used to compare the parallel code with scaled roughly as  $\mathcal{O}(N^{2.2})$ .

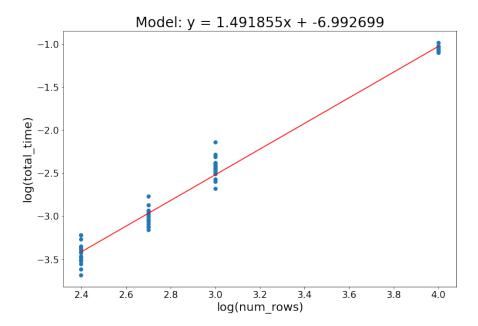

Figure 2: Plotting the runtime of the program as a function of the number of rows N (on a log-log scale), we find that the total runtime scales as  $\mathcal{O}(N^{1.5})$ , which is less than the expected  $\mathcal{O}(N^2)$ . Note the plot is generated with data for a constant amount of threads, which in this case is 4.

Looking at the scaling instead for a constant number of rows (here we are using 10000), we find there is no real scaling. Ideally we would like to see the total runtime decrease as we increase the number of threads, but this is not the case for the algorithm being used here.

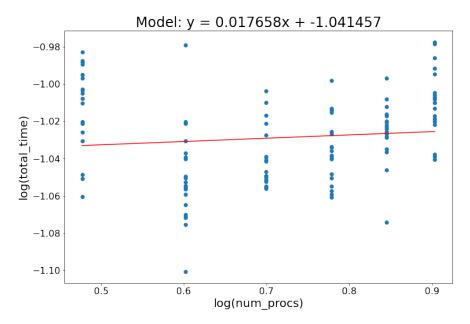

Figure 3: Plotting the runtime of the program as a function of the number of threads *P* (on a log-log scale). The linear fit is not ideal, such that it is fair to conclude that there is no note worthy scaling with the number of processors. Again it is worth noting that the plot has been generated for a constant number of rows which was taken to be 10000.

As discussed in lecture, the efficiency of our algorithm is less than ideal, which is supported by the calculations in Table 1 (see Appendix A for details on how these values were calculated). We see that running the code across 3 threads yields superlinear scaling, and our program is more efficient than the serial code. However, as the number of threads increase, we start seeing diminishing returns in terms of the speedup, and so our efficiency starts dropping dramatically. At 8 concurrent threads, our code is less than half as efficient as the serial code, and it is actually slower than the case with only 3 threads (in reality they are approximataly equal in runtime, but the linear model predicted it would be slower).

If we wanted to write a program to do matrix vector multiplication in parallel more efficiently, it would be best to have a shared pool of memory that each process can read and write to at the same time. This could be done by adding a single line to the serial code and using OpenMP.

Number of Threads	Speedup	Scaling Factor a	Efficiency
3	3.92	1.31	1.31
4	3.76	0.94	0.94
5	3.61	0.72	0.72
6	3.47	0.58	0.58
7	3.33	0.48	0.48
8	3.19	0.40	0.40

Table 1: Summary of the speedup and efficiency of our matrix vector multiplication code. These values are taken for a constant number of rows N = 10000.

```
// Matrix-vector multiplication code Ab=c //
    // Note that I will index arrays from 0 to n-1.
    // Here workers do all the work and boss just handles collating results
    // and sending info about A.

227
```

#### 2 Matrix Matrix Multiplication Using MPI

Our second task is to generalize the matrix vector product code to perform matrix matrix products. The modified code can be seen below, while a demonstration that the code works correctly can be seen in Figure 4. The serial code that will be used for comparison was written using the DGEMM\_ function from the BLAS library.

```

Figure 4: Demonstration of the code working. In the first example, the first matrix is taken to be the identity and the second has consecutive integers along the main diagonal. In the second example, the first matrix is changed to the reverse identity (1s along the antidiagonal). In both cases, we get the expected result.

The modified code for matrix multiplication scales as  $\mathcal{O}(N^{3.3})$ , where N is the number of rows as can be seen in Figure 5. This is slightly more than the expected  $\mathcal{O}(N^3)$ . It should be noted that the serial code scaled as  $\mathcal{O}(N^{2.9})$ , which is slightly less than expected. It is also interesting that the current world record (as of 2020) for the asympotite scaling of matrix matrix multiplication has been shown to be of the order  $\mathcal{O}(N^{2.3728596})$  by Josh Alman and Virginia Vassilevska Williams (arXiv:2010.05846).

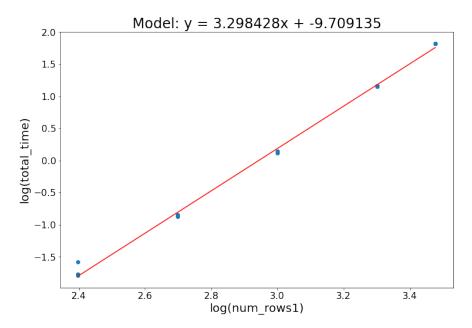

Figure 5: Plotting the runtime of the program as a function of the number of rows N (on a log-log scale), we find that the total runtime scales as  $\mathcal{O}(N^{3.3})$ , which is slightly more than the expected  $\mathcal{O}(N^3)$ .

More importantly for our purposes, we find that the total runtime scales as  $\mathcal{O}(P^{-1})$ , where P is the total number of threads (for a fixed number of rows N). This is the expected result as we discussed in lecture: for large N, we expect the speedup to approach P, which is supported by Figure 6 and Table 2.

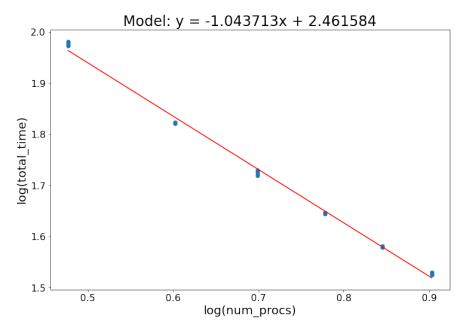

Figure 6: Plotting the runtime of the program as a function of the number of threads P, we find the scaling for a fixed number of rows N (here N=3000) to be of the order  $\mathcal{O}(P^{-1})$ 

Number of Threads	Speedup	Scaling Factor a	Efficiency
3	1.66	0.55	0.55
4	2.24	0.56	0.56
5	2.83	0.57	0.57
6	3.42	0.57	0.57
7	4.02	0.57	0.57
8	4.62	0.58	0.58

Table 2: Summary of the speedup and efficiency of our matrix multiplication code. These values are taken for a constant number of rows N = 3000.

# 3 Matrix Matrix Multiplication Using MPI and BLAS

In this section, we modify the code to compute the matrix matrix porduct from above. Instead of computing the product of a row from the first matrix and a column of the second matrix manually, we substitute the DDOT\_ function from the BLAS library. As we did for the previous code, we test the code still works as can be seen in Figure 7.

```

```

Figure 7: Demonstration of the code working. Just as we did for the non-BLAS implementation, the first example takes the first matrix to be the identity while the second has consecutive integers along the main diagonal. In the second example, the first matrix is changed to the reverse identity (1s along the antidiagonal). In both cases, we get the expected result.

The new code using BLAS shows that the total runtime as a function of the number of rows N scales as  $\mathcal{O}(N^{3.6})$  as supported by Figure 8. This is peculiar since this means the modified code using BLAS actually scales worse than the non-BLAS code.

Perhaps this is because the BLAS code doesn't actually scale in polynomial time and is instead scaling like  $\mathcal{O}(N^{\alpha}\log N)$  for some  $\alpha$ , but I am not confident enough to say for certain<sup>1</sup>. I would expect the BLAS code to scale better than the non-BLAS code, and given that the linear regression does not fit as nicely as it did for the non-BLAS case, I suspect this may be the case.

<sup>&</sup>lt;sup>1</sup>If there is a more obvious or apparent reason for this behaviour, I'd be interested to know.

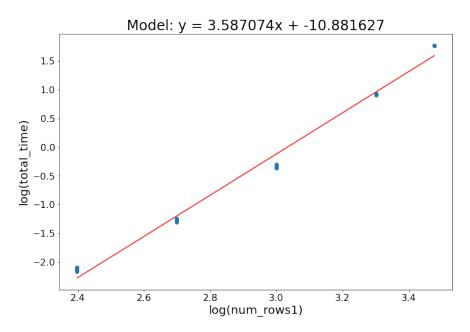

Figure 8: Plotting the runtime of the program as a function of the number of rows N (on a log-log scale), we find that the total runtime scales as  $\mathcal{O}(N^{3.6})$ , which again is more than the expected  $\mathcal{O}(N^3)$ , and even worse than the non-BLAS scaling.

Considering now the scaling as a function of the number of threads P, we again find a similar result: that for a fixed number of rows N, the scaling goes as  $\mathcal{O}(P^{-1})$ , as can be seen in Figure 9. This is once again good news and agrees with what we would expect: the scaling should still be the same as in the non-BLAS case.

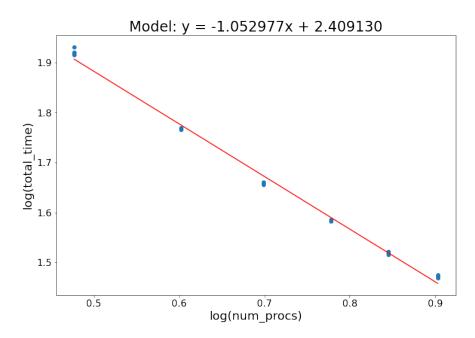

Figure 9: Plotting the runtime of the program as a function of the number of threads P, we find the scaling for a fixed number of rows N (here N=3000) to be of the order  $\mathcal{O}(P^{-1})$ 

Looking at the speedup and efficiency as seen in Table 3, we see that our BLAS code runs faster than the non-BLAS code and is therefore more efficient as well. It also appears that that efficiency of the program increases as we allocate more threads. As a test, I ran the code with N=3000 rows and P=12 threads, and found the efficiency to drop off slightly to 0.59.

Number of Threads	Speedup	Scaling Factor a	Efficiency
3	2.05	0.63	0.63
4	2.65	0.64	0.64
5	3.22	0.65	0.65
6	3.80	0.65	0.65
7	4.35	0.66	0.66
8	4.90	0.66	0.66

Table 3: Summary of the speedup and efficiency of our matrix matrix multiplication code using the BLAS DDOT\_ function. These values are taken for a constant number of rows N=3000.

I would expect if we ran the code for say N=5000, the efficiency would be much higher, since if we look at the efficiency for N=2000, as in Table 4, we see that the efficiency of the program nearly doubles going from N=2000 to N=3000. As a test, I ran the serial code for N=5000, which took 1083.20 seconds. The parallel code ran with P=12 took 128.45 seconds, corresponding to a speedup of 8.43 and an efficiency of 0.70. When run with P=8 instead, it took 188.57 seconds, giving a speedup of 5.74 and an efficiency of 0.72.

Number of Threads	Speedup	Scaling Factor a	Efficiency
3	1.16	0.39	0.39
4	1.52	0.38	0.38
5	1.87	0.37	0.37
6	2.22	0.37	0.37
7	2.56	0.37	0.37
8	2.90	0.36	0.36

Table 4: Summary of the speedup and efficiency of our matrix matrix multiplication code using the BLAS DDOT\_ function. These values are taken for a constant number of rows N = 2000.

### 4 Solving Poisson's Equation Using LAPACK

The last part of the assignment is a brief introduction to the LAPACK library. The code being tested solves the Poisson equation  $\nabla^2 U(\vec{x}) = f(\vec{x})$ . In Figure 10, I have run the provided code and plotted the solution using plotly in Python.

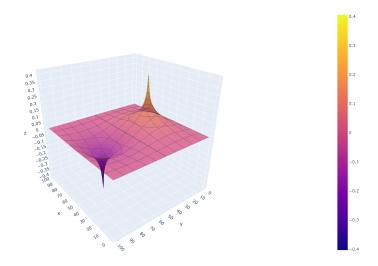

Figure 10: Plot of the solution using N = 100 sites.

Testing the run time of the code as a function of the number of sites N, the scaling is found to be of the order  $\mathcal{O}(N^{3.8})$ , as can be seen in Figure 11. The scaling can be expected to be  $\mathcal{O}(N^4)$ , as performing a PLU factoraization scales as  $\mathcal{O}(N^3)$ , and back-substitution should contribute a factor proportional to  $\mathcal{O}(N)$ . Given we are using BLAS routines which are optimized for banded and positive definite matrices, it is convincing our scaling should be slightly less than the worst case scenario of  $\mathcal{O}(N^4)$ .

Using the linear regression model (red line) in the plot, we can estimate that the largest system that can be solved (on my hardware) in 5 minutes to be roughly N=975. This seems reasonable, since the runtime for a system with N=1000 was roughly 385 seconds.

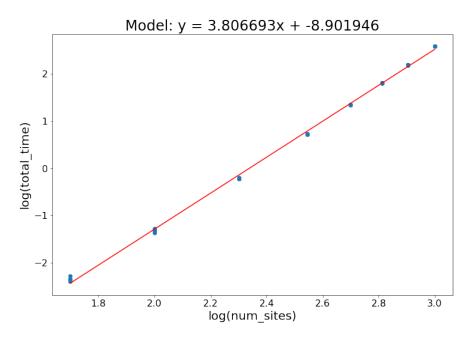

Figure 11: Plotting the runtime of the program as a function of the number of sites N (on a log-log scale), we find that the total runtime scales as  $\mathcal{O}(N^{3.8})$ .

#### A Jupyter Notebook

Below is an example notebook I have used in order to generate and analyze my timing data. The notebook will compile and run the given program a number of times for various numbers of threads and matrix dimensions. It then creates linear regression models from the data which can be used to determine the speedup and efficiency of parallelization.

# plots
